

AI Code Analysis Report

Language: Python

Score: 8/10

Severity: Low

Complexity: Low

Summary

The code defines a class `Student` with an initializer that sets the student's name and a method to display this name. It then creates an instance of `Student` named 'Tripti' and calls the `display` method to print her name.

Bugs

Improvements

- {'description': 'The code could benefit from adding error handling to ensure that the input is a string for the student's name.', 'impact': 'If non-string values are passed, it will raise a TypeError.'}
- {'description': 'Adding type hints can improve code readability and maintainability.', 'impact': 'It helps other developers understand what types of data should be used in method arguments and return values.'}

Best Practices

- {'description': 'Using a class for such a simple structure could lead to unnecessary complexity. For this case, a function might suffice.', 'impact': 'This would make the code more modular and easier to test.'}
- {'description': 'Adding docstrings to the methods can help other developers understand what the method does without having to look at the implementation details.', 'impact': 'It enhances maintainability and readability.'}
